

Number 319 • April 24, 2001

1999 National Hospital Discharge Survey

by Jennifer R. Popovic and Margaret J. Hall, Division of Health Care Statistics

This report presents the most current nationally representative data on inpatient care in the United States. Data are from the National Hospital Discharge Survey (NHDS), the longest continuously running nationally representative survey of hospital utilization.

The figure on the right shows trends in discharges and days of care from NHDS from 1965 through 1999, the most current year of data. In 1999, there were 32.1 million discharges that resulted in 160.1 million days of care. Numbers of discharges and days of care peaked in the early 1980's. The drop in number of discharges is partly accounted for by an increase in ambulatory or same-day surgery visits. The decline in number of days of care is partly due to the decline in the number of inpatients, but it is also a result of reduced lengths of stay for hospital inpatients. The average length of stay for inpatients in 1980 was 7.3 days. In 1999, the average length of stay for inpatients was 5.0 days.

Trends in inpatient utilization, 35 years of hospital care: United States, 1965–99

This report presents information about hospital utilization during 1999 as well as trend data for selected variables. Additional information about hospital utilization is available from the National Center for Health Statistics (NCHS) website: <http://www.cdc.gov/nchs>.

Individual-year public-use data files are available for download from the website, and a multiyear public-use data file for trend analysis is available on CD-ROM. These and other products can be obtained by contacting the NCHS Data Dissemination Branch at 301.458.INFO or by email at NCHSquery@cdc.gov.

KEYWORDS: Inpatients • diagnoses • procedures • ICD-9-CM

Acknowledgments

This report was prepared in the Division of Health Care Statistics. Staff in the Hospital Care Statistics Branch verified the data. Rong Cai, of the OAO Corporation, was contracted to produce estimated parameters for relative standard error equations; she also performed the computer programming for the report. This report was edited by Klaudia M. Cox and typeset by Jacqueline M. Davis of the Publications Branch, Division of Data Services.

Abstract

Objectives—This report presents national estimates of the use of non-Federal short-stay hospitals in the United States during 1999. Numbers and rates of discharges, diagnoses, and procedures are shown by age and sex. Discharges are also shown by geographic region of hospital. Average lengths of stay are presented for all discharges and for selected diagnostic categories by age and by sex. Trend data for selected variables are also provided.

Methods—The estimates are based on medical abstract data collected through the National Hospital Discharge Survey for 1999. The survey has been conducted annually by the National Center for Health Statistics since 1965. Diagnoses and procedures presented are coded according to the *International Classification of Diseases, 9th Revision, Clinical Modification*, or ICD-9-CM.

Results—Trends in the utilization of non-Federal short-stay hospitals show that the number of discharges and days of care peaked in the early 1980's. The number of discharges stabilized during the 1990's while the number of days of care continued to steadily decrease. In 1999, there were an estimated 32.1 million discharges of inpatients, excluding newborn infants, from non-Federal short-stay hospitals in the United States. The discharge rate was 1,166.2 per 10,000 population and the average length of stay was 5.0 days. The discharge rate among persons 65 years of age and over increased 11 percent from 1990 to 1999. Among persons 15–44 years of age, the discharge rate decreased 17 percent between 1990 and 1999, and among 45–64 year-olds, the discharge rate between 1990 and 1999 decreased 14 percent. There were 41.3 million procedures performed on hospital inpatients during 1999. Men had more cardiovascular procedures than women did (3.5 million versus 2.6 million), while women had more operations on the digestive system than men did (3.0 million versus 2.2 million). About one-quarter of all procedures performed on women were obstetrical.

Introduction

This report presents data from the 1999 National Hospital Discharge Survey (NHDS). The survey has been conducted continuously by the National Center for Health Statistics (NCHS) since 1965. National estimates of hospital use derived from NHDS are published by NCHS for each calendar year. This report provides an overview of the 1999 data, including the number and rate of discharges and average lengths of stay by the age and sex of patients and by geographic region of hospital. Average lengths of stay are also presented for selected diagnostic categories. Estimates for the number and rate of selected procedures performed on hospital inpatients are shown by age and sex. More detailed data from NHDS are published in Series 13 of *Vital and Health Statistics*, which includes two reports on trends in hospital use (1,2).

NHDS is the principal source for national data on the characteristics of patients discharged from non-Federal short-stay hospitals. Data from NHDS are used to examine important topics of interest in public health and health services research (3–19) and for a variety of activities by governmental, scientific, academic, and commercial institutions.

Estimates of the number of procedures shown in this report are for inpatients only. Data on ambulatory surgery are available from the National Survey of Ambulatory Surgery (NSAS), also conducted by NCHS. NSAS was conducted from 1994 through 1996 and covers hospital-based and free-standing ambulatory surgery centers. Data from the 3 years of this survey have been published (20–25).

Information on ambulatory procedures is also collected in two other NCHS surveys. The National Ambulatory Medical Care Survey obtains information on procedures ordered or performed during visits to physicians' offices (26). The National Hospital Ambulatory Medical Care Survey collects data on procedures ordered or performed during visits to hospital outpatient and emergency departments (27,28).

Highlights

Patient and hospital characteristics

- Trends in hospital utilization show that the number of discharges and days of care peaked in the early 1980's. The number of discharges stabilized during the 1990's, while the number of days of care continued to steadily decrease.
- In 1999, there were an estimated 32.1 million discharges of inpatients, excluding newborn infants, from non-Federal short-stay hospitals in the United States ([table 1](#)).
- The discharge rate was 1,166.2 per 10,000 population and the average length of stay was 5.0 days in 1999 ([table 1](#)).
- The discharge rate per 10,000 population was 946.8 for men and 1,375.8 for women. Men had an average length of stay of 5.4 days compared with 4.7 days for women.
- The discharge rate among persons 65 years of age and over increased 11 percent from 1990 to 1999 ([figure 1](#)).
- The discharge rate among persons 15–44 years old decreased 17 percent from 1990 to 1999, and the discharge rate among persons 45–64 years of age decreased 14 percent from 1990 to 1999 ([figure 1](#)).
- Persons 65 years of age and over accounted for 39.5 percent of all discharges ([table 1](#)).
- The discharge rate per 10,000 population ranged from 1,331.6 in the Northeast region to 934.2 in the West. The average length of stay ranged from 5.7 days in the Northeast region to 4.6 days in the West.

Diagnoses

- Over half of all first-listed diagnoses were in four ICD-9-CM chapters: diseases of the circulatory system, supplementary classifications (including females with deliveries), diseases of the respiratory system, and diseases of the digestive system ([table 2](#)).
- Six diagnostic categories each accounted for more than a million discharges. These were heart disease

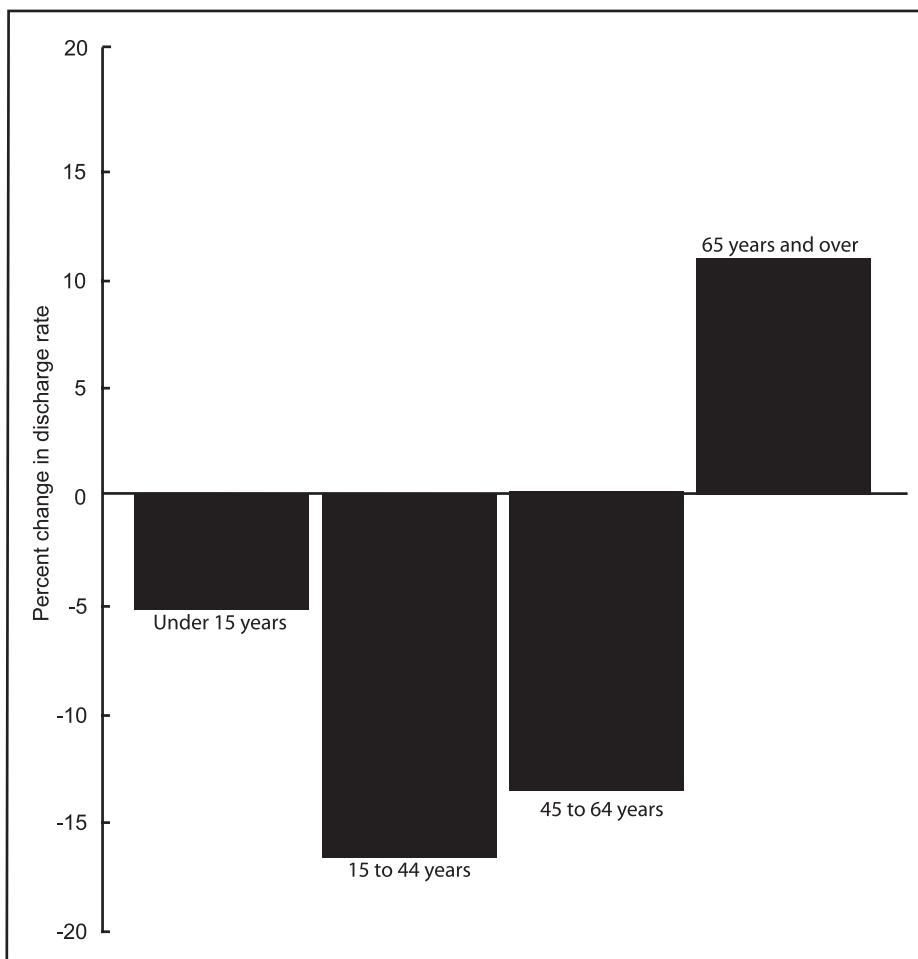

Figure 1. Percent change in discharge rate by age: United States, 1990–99

(4.5 million), delivery (3.8 million), pneumonia (1.4 million), malignant neoplasms (1.3 million), psychoses (1.3 million), and fractures (1.0 million). Coronary atherosclerosis, a type of heart disease, accounted for 1.2 million discharges and over 25 percent of all heart disease diagnoses (figure 2).

- The average length of stay was 2.5 days for delivery, 4.7 days for heart disease, 5.5 days for fractures, 6.0 days for pneumonia, 7.0 days for malignant neoplasms, and 8.4 days for psychoses (table 4) (figure 3).
- For persons 65 years of age and over, there were 843.7 discharges per 10,000 population with a first-listed diagnosis of heart disease (table 3).
- The number and rate of coronary atherosclerosis diagnoses more than doubled during the 1990's. Among persons 65 years of age and over, the number and rate more than tripled during this time (figure 4).

Procedures

- During 1999, 41.3 million procedures were performed on hospital inpatients (table 8).

- Almost three-fourths of all procedures were in four ICD-9-CM chapters: miscellaneous diagnostic and therapeutic procedures, obstetrical procedures, operations on the cardiovascular system, and operations on the digestive system (figure 5).
- About one-quarter of all procedures performed on women were obstetrical (table 10) (figure 5).
- Males had more cardiovascular procedures than females did (3.5 million versus 2.6 million), while females had more operations on the digestive system than males (3.0 million versus 2.2 million) (table 10) (figure 5).
- Frequent procedures for males were arteriography and angiography, cardiac catheterization, removal of coronary artery obstruction and insertion of stent(s), respiratory therapy, diagnostic ultrasound, and computerized axial tomography.
- Frequent procedures for females were repair of current obstetric laceration, episiotomy, arteriography and angiography, cesarean section, artificial rupture of membranes, hysterectomy, and diagnostic ultrasound.

Methods

Data source

The National Hospital Discharge Survey (NHDS) collects data from a sample of inpatient records acquired

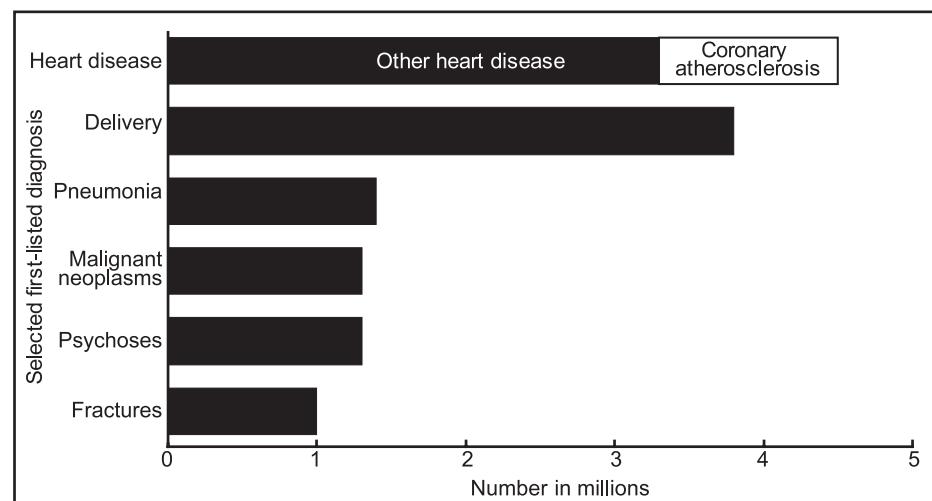

Figure 2. Number of selected first-listed diagnoses for hospital discharges: United States, 1999

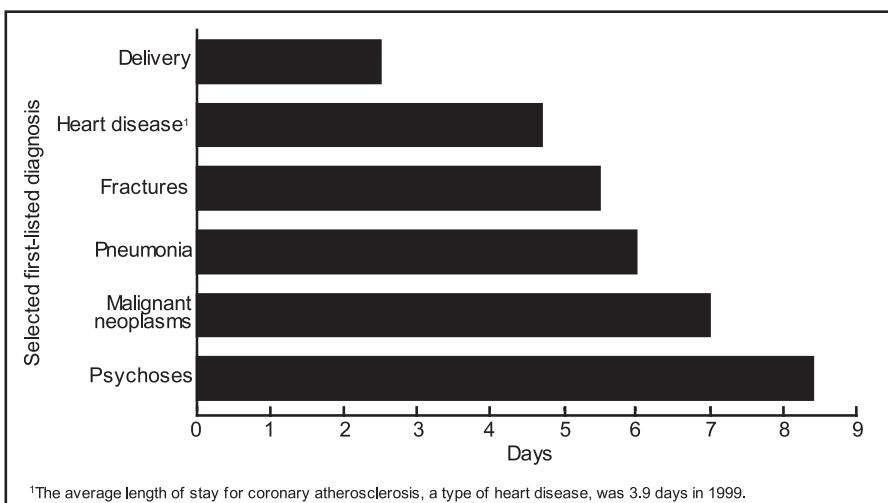

Figure 3. Average length of hospital stay for discharges with selected first-listed diagnoses: United States, 1999

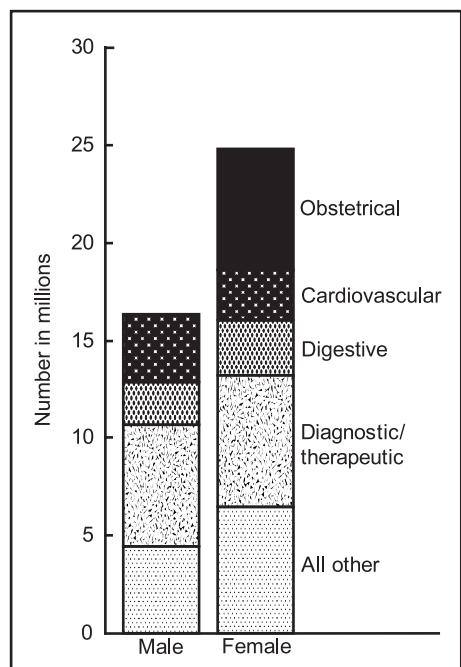

Figure 5. Number of all-listed inpatient procedures by sex: United States, 1999

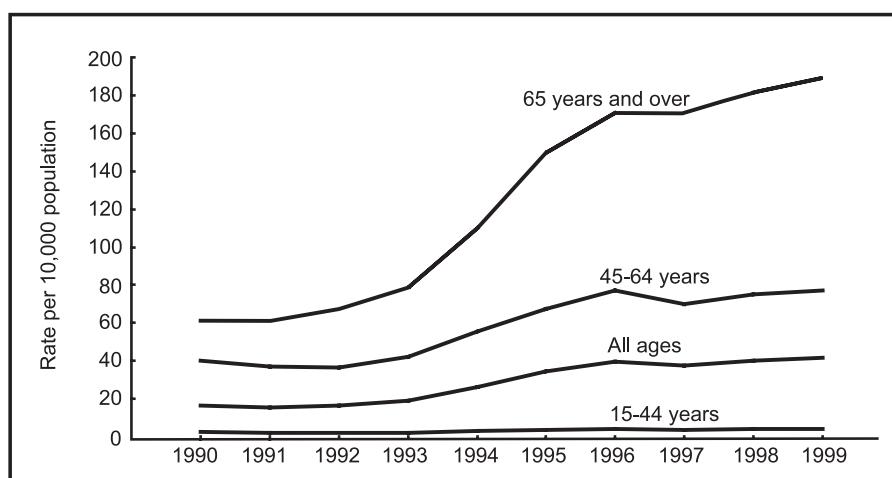

Figure 4. Rate of discharges for coronary atherosclerosis by age group, 1990–99

from a national sample of hospitals. Because persons with multiple discharges during the year may be sampled more than once, estimates are for discharges, not persons. Only hospitals with an average length of stay of fewer than 30 days for all patients, general hospitals, or children's general hospitals are included in the survey. Federal, military, and Department of Veterans Affairs hospitals, as well as hospital units of institutions (such as prison hospitals), and hospitals with fewer than six beds staffed for patient use, are excluded.

Prior to 1988, NHDS utilized a two-stage design, but in 1988 the survey was redesigned (29). Beginning in 1988, the largest hospitals were included in the sample with certainty, while the

remaining sample of hospitals was based on a stratified three-stage design. The first stage consisted of a selection of 112 primary sampling units (PSU's) that comprised a probability sample of PSU's used in the 1985–94 National Health Interview Survey (30). The second stage consisted of a selection of noncertainty hospitals from the sampled PSU's. At the third stage, a sample of discharges within hospitals was selected by a systematic random sampling technique. The sampling frame for hospitals drawn under the new design has been the SMG Hospital Market Database (31).

For 1999, the sample consisted of 513 hospitals, of which 26 were found to be out of scope (ineligible) because they had gone out of business or

otherwise failed to meet the criteria for the NHDS universe. Of the 487 in-scope (eligible) hospitals, 458 (94.0 percent) responded to the survey. Data were collected for approximately 300,000 discharges from the 458 responding hospitals.

Two data collection procedures were used in the survey. One was a manual system in which sample selection and medical transcription from the hospital records to abstract forms were performed by the hospital's staff or by staff of the U.S. Bureau of the Census on behalf of NCHS. Completed forms were sent to NCHS for coding, editing, and estimation.

The other data collection procedure was an automated system in which NCHS purchased machine-readable medical record data from commercial organizations, State data systems, hospitals, or hospital associations. Records from these sources were systematically sampled by NCHS. In 1999, approximately 40 percent of respondent hospitals provided data through the automated system. A detailed report on the design and operation of NHDS has been published (29).

The medical abstract form and the automated data contain items that relate

to the personal characteristics of the patient. These items include birth date (or age), sex, race, ethnicity, marital status, ZIP Code, and expected sources of payment. Administrative items such as admission and discharge dates, discharge status, and medical record number were also included. The medical information about patients includes up to seven diagnoses, as many as four surgical and nonsurgical operations and procedures, and dates of surgery. (The medical record number, date of birth, and ZIP Code are confidential information not available to the public.) Medical data are coded according to the *International Classification of Diseases, 9th Revision, Clinical Modification* (ICD-9-CM) (32). Definitions of the terms used in this report have been published (29).

For the manual data collection, an ongoing quality control program was undertaken on the coding and entering of data from abstracts to electronic form. Approximately 10 percent of the abstracts are independently recoded by an NHDS coder, with discrepancies resolved by the chief coder. The overall error rate for records manually coded for the 1999 data year was 0.6 percent for medical (ICD-9-CM) coding and keying and 0.3 percent for demographic coding and keying.

Estimation

Because of the complex multistage design of NHDS, the survey data must be inflated or weighted in order to produce national estimates. The estimation procedure produces essentially unbiased national estimates and has three basic components: (a) inflation by reciprocals of the probabilities of sample selection, (b) adjustment for nonresponse, and (c) population weighting ratio adjustments. These three components of the final weight are described in more detail in another report (29).

The standard error is primarily a measure of sampling variability that occurs by chance because only a sample rather than the entire universe is surveyed. Estimates of the sampling variability for this report were calculated

with SUDAAN software, which takes into account the complex sample design. A description of the software and the approach it uses has been published (33). The standard errors of statistics for the 1999 NHDS Advance Data are included in each of the tables.

Use of tables

Discharges are shown in this report by first-listed diagnosis. This is the principal diagnosis if it is specified on the medical record. If the principal diagnosis is not specified, the diagnosis listed first on the face sheet or discharge summary of the medical record is used. Estimates of procedures, including surgical or nonsurgical operations, diagnostic procedures, and special treatments reported on the medical record are also published. Up to four procedures were coded for each discharge. All-listed procedures include all occurrences of the procedure coded regardless of the order on the medical record.

The diagnoses and procedures appear in separate tables of this report, presented by chapter of ICD-9-CM. Within these chapters, subcategories of diagnoses or procedures are shown. These specific categories were selected primarily because of their large estimates or because they are of special interest. Although diagnoses assigned ICD-9-CM codes E800–E999 (Supplementary classification of external causes of injury and poisoning) were included in NHDS, these diagnoses were excluded from this report. Data for newborn infants, defined as patients admitted to a hospital by birth, were also excluded from this report.

Because of low reliability, estimates with a relative standard error of more than 30 percent or that are based on a sample of fewer than 30 records are replaced by asterisks (*). Estimates based on 30–59 patient records are preceded by an asterisk to indicate that they also have low reliability.

Estimates have been rounded to the nearest thousand. Therefore, figures within tables do not always add to the totals. Rates and average lengths of stay were calculated from unrounded figures

and may not precisely agree with rates or average lengths of stay calculated from rounded data.

The population estimates used in computing rates are based on U.S. Bureau of the Census estimates of the civilian population of the United States as of July 1, 1999. Figures are consistent with national population estimates in US-99-SIS-7 (U.S. Population Estimates by Age, Sex, Race, and Hispanic Origin: 1999) and have been adjusted for net underenumeration using the 1990 National Population Adjustment Matrix.

Facilities are classified by location in one of the four geographic regions of the United States that corresponds to those used by the U.S. Bureau of the Census.

<i>Region</i>	<i>States included</i>
Northeast	Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania
Midwest	Michigan, Ohio, Illinois, Indiana, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas
South	Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Louisiana, Oklahoma, and Texas
West	Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Washington, Oregon, California, Hawaii, and Alaska
